AUTO TICKET CLASSIFICATION USING FLOW DESIGNER

2. Requirement Analysis Phase

The Requirement Analysis Phase is the stage in which the ideas identified during brainstorming are converted into clear and implementable system requirements. For the "Auto Ticket Classification using FLOW DESIGNER" project, the main objective of requirement analysis is to understand what the ServiceNow application must do when a student or staff member creates an IT support ticket. The requirements must be specific enough to guide the configuration of the ticket form, dependent choices, Flow Designer workflow, notifications, testing, and security controls.

The first requirement identified is the need for a suitable ticket creation mechanism. The user should be able to provide the basic information required for raising an IT support request. The ticket should contain a short description of the problem so that the system and the support team can understand the nature of the request. The form should be simple and should avoid unnecessary fields that could confuse the user. At the same time, the information captured should be structured enough for the helpdesk team to process the request efficiently.

The second major requirement is ticket classification. The system should classify or organize the ticket according to the information entered by the user. The project is designed around the use of predefined choices rather than requiring the helpdesk staff to manually interpret every request. The classification logic should be consistent and should ensure that the ticket receives the appropriate category or related value based on the configured conditions. This requirement is important because accurate categorization can help the support team understand the type of issue and determine the next step in the support process.

A related requirement is the implementation of dependent choice behavior. Dependent choices allow one selection to control the available options in another field. For example, when a particular issue category is selected, the next field can display only the relevant subcategories. This improves data quality because users are guided toward valid combinations of values. It also makes the form easier to use and reduces the chance of selecting an unrelated subcategory. The

requirement analysis therefore includes identifying the parent choices, dependent choices, and the relationship between them.

Another requirement is workflow automation through ServiceNow Flow Designer. The flow should be triggered when the required ticket event occurs, such as the creation or submission of a new ticket. After the trigger, the flow should evaluate the required conditions and perform the configured actions. These actions may include updating ticket information, applying the appropriate classification, and generating a notification. The flow should be designed in a clear sequence so that each step can be tested independently and maintained as

The requirement analysis should include administrator requirements as well. Administrators should be able to understand the configured fields, choices, conditions, flows, and notifications. Proper naming and documentation should make the system easier to manage and troubleshoot when changes are required.

The system should also consider the reliability of automated processing. The classification and notification workflow should continue to operate consistently for multiple tickets. The same input conditions should produce the same expected result, reducing dependency on manual intervention.

Testing should include different user scenarios and ticket types. Tickets created for different IT problems should be tested to verify that the correct category, dependent choice, classification, and notification are applied. The testing process should also verify that unexpected or invalid inputs are handled correctly.

The requirement analysis should provide a clear foundation for future development. All functional and non-functional requirements identified during this phase should be documented before implementation begins. This helps the development team configure the ServiceNow application according to a defined structure and reduces the possibility of missing important requirements during implementation.

Security is another requirement considered during analysis. Users should have only the access necessary to create or view tickets, while configuration and administrative functions should remain available to authorized users. The system should protect ticket information and maintain

data integrity. Testing should verify that unauthorized changes cannot be made through normal user access and that the workflow operates within the intended permissions.

The requirement analysis should provide a clear foundation for future development. All functional and non-functional requirements identified during this phase should be documented before implementation begins. This helps the development team configure the ServiceNow application according to a defined structure and reduces the possibility of missing important requirements during implementation.

Finally, the requirements identified in this phase provide the foundation for implementation and validation. They define the functional behavior of the ticket form, classification logic, dependent choices, automated flow, notification process, data validation, error handling, ticket tracking, security, performance, usability, and testing. By completing requirement analysis before configuration, the project can be developed in a controlled and systematic manner. The result is a clear specification for building an automated ServiceNow solution that reduces manual effort and supports efficient IT ticket management in a school environment.
